

Second Partial Derivatives

We will use δ to denote partial derivatives

Suppose we have a string fixed at $x = 0$ and $x = 1$.

Let $\mathbf{h(x, t)} := \cos(t) \cdot \sin(\pi x)$ be the height of the string at pt x at time t .

Below is the string at $t = 0$.

[See the Animation String Vibration for the motion of the string](#)

[See also the Animation - String in 3-d which shows the motion if we could see in time as well as space.](#)

We have discussed the partial derivatives and will interpret them in terms of this vibrating string.

We will also introduce and discuss the second partial derivatives.

1. $\frac{\partial \mathbf{h}}{\partial \mathbf{x}}$

For each fixed time t_0 $\mathbf{h} = \mathbf{h(x, t_0)}$ is a function of a single variable x . Therefore $\frac{\partial \mathbf{h}}{\partial \mathbf{x}}$ **is simply the slope of the tangent line at each (x)** . Below we see the tangent lines at $x = 1/4$ and $3/4$.

$\frac{\partial h}{\partial x} = \pi \cos(t_0) \cdot \cos(\pi x)$ Note $\frac{\partial h}{\partial x} > 0$ when both have the same sign and $\frac{\partial h}{\partial x} < 0$ when they have different signs

$$0 \leq t \leq \pi/2$$

Note that $\frac{\partial h}{\partial x} > 0$ if $0 \leq x \leq 1/2$ and the slope of the tangent line is positive. $\frac{\partial h}{\partial x} < 0$

if $1/2 \leq x \leq 1$ and the slope of the tangent line is negative.

For $\pi/2 \leq t \leq 3\pi/2$ this reverses.

For $3\pi/2 \leq t \leq 2\pi$ the situation is the same as for $0 \leq t \leq \pi/2$.

[See the Animation Vibrating String with Tangent Line](#)

$$2. \frac{\delta^2 \mathbf{h}}{\delta t \cdot \delta x}$$

As the animation shows at each fixed x the tangent line changes in time. This is precisely what we mean

by $\frac{\delta}{\delta t} \left(\frac{\delta \mathbf{h}}{\delta x} \right) = \frac{\delta^2 \mathbf{h}}{\delta t \cdot \delta x}(\mathbf{x}, t)$ -- the rate at which the slope of the tangent line at each x changes. This is one of four second partial derivatives and is one of two mixed partial derivatives.

$$\frac{\delta^2 \mathbf{h}}{\delta t \cdot \delta x} = -\pi \sin(t) \cdot \cos(\pi x)$$

If we focus in on $x = .25$

$$0 < t < \pi \quad \frac{\delta^2 \mathbf{h}}{\delta t \delta x} < 0 \quad \text{so the slope of the tangent line is decreasing}$$

$$\pi < t < 2\pi \quad \frac{\delta^2 \mathbf{h}}{\delta t \delta x} > 0 \quad \text{so the slope of the tangent line is increasing}$$

You may want to view the animation [Vibrating String with Tangent Line](#) again.

Note the order of differentiation is right to left. If we use our subscript notation for partial differentiation

we write f_{xt} and the order of differentiation is read left to right.

(The order of differentiation actually turns out not to matter if f and its first and second mixed partial derivatives are all continuous.)

$$3. \frac{\delta^2 \mathbf{h}}{\delta \mathbf{x}^2}$$

Recall $\frac{\delta \mathbf{h}}{\delta \mathbf{x}}$ is the slope of the tangent line at each x for fixed time t_0 . Then $\frac{\delta}{\delta \mathbf{x}} \left(\frac{\delta \mathbf{h}}{\delta \mathbf{x}} \right) = \frac{\delta^2 \mathbf{h}}{\delta \mathbf{x}^2}$

is the concavity of the string. $\frac{\delta^2 \mathbf{h}}{\delta \mathbf{x}^2} = -\pi^2 \cdot \cos(t) \cdot \sin(\pi x)$. Note $\sin(\pi x) > 0$ for all x so the sign of $\frac{\delta^2 \mathbf{h}}{\delta \mathbf{x}^2}$

is determined by the term $-\pi^2 \cdot \cos(t)$

$0 < t < \pi/2$ $\frac{\delta^2 \mathbf{h}}{\delta \mathbf{x}^2} < 0$ and at every pt (except the endpoints) The shape of the string is concave down.

$\pi/2 < t < 3\pi/2$ $\frac{\delta^2 \mathbf{h}}{\delta \mathbf{x}^2} > 0$ and at every pt (except the endpoints) The shape of the string is concave up.

$3\pi/2 < t < 2\pi$ $\frac{\delta^2 \mathbf{h}}{\delta \mathbf{x}^2} < 0$ and at every pt (except the endpoints) The shape of the string is concave down.

[Again See the Animation Vibrating String with Tangent Line](#)

$$4. \frac{\delta \mathbf{h}}{\delta \mathbf{t}}$$

This time we fix $x = x_0$ so $\frac{\delta \mathbf{h}}{\delta \mathbf{t}}$ is the velocity of the pt on the string $h(x_0, t)$.

$$\frac{\delta \mathbf{h}}{\delta \mathbf{t}} = -\sin(t) \cdot \sin(\pi x)$$

$\frac{\delta \mathbf{h}}{\delta \mathbf{t}} < 0$ for $0 < t < \pi$ the particle is moving down

$\frac{\delta \mathbf{h}}{\delta \mathbf{t}} > 0$ for $\pi < t < 2\pi$ the particle is moving up

Note for a single particle on the string the motion is analogous to the motion of a mass on a spring

[See the Animation String Velocity.](#)

5. $\frac{\delta^2 \mathbf{h}}{\delta t^2}$

Simply $\frac{\delta^2 \mathbf{h}}{\delta t^2} = \frac{\delta}{\delta t} \left(\frac{\delta \mathbf{h}}{\delta t} \right)$ is the rate of change of the velocity of a single particle i.e. the acceleration.

$$\frac{\delta^2 \mathbf{h}}{\delta t^2} = -\cos(t) \cdot \sin(\pi x)$$

Recall from one dimensional motion that a particle speeds up when the velocity and acceleration have the same sign and the particle is slowing down when the velocity and acceleration have opposite signs.

The velocity is $\frac{\delta \mathbf{h}}{\delta t} = -\sin(t) \cdot \sin(\pi x)$ and the acceleration is $\frac{\delta^2 \mathbf{h}}{\delta t^2} = -\cos(t) \cdot \sin(\pi x)$

In the animation we focus on $x = .25$, however what is true at $x = .25$ is true for all x .

$0 < t < \pi/2$ $\frac{\delta^2 \mathbf{h}}{\delta t^2}$ and $\frac{\delta \mathbf{h}}{\delta t}$ are both negative so the particle is moving down and speeds up

$\pi/2 < t < \pi$ $\frac{\delta^2 \mathbf{h}}{\delta t^2} > 0$ and $\frac{\delta \mathbf{h}}{\delta t} < 0$ so the particle slows down and comes to a stop at $t = \pi$.

$\pi < t < 3\pi/2$ $\frac{\delta^2 \mathbf{h}}{\delta t^2}$ and $\frac{\delta \mathbf{h}}{\delta t}$ are both positive so the particle starts moving up picking up speed

$3\pi/2 < t < 2\pi$ $\frac{\delta^2 \mathbf{h}}{\delta t^2} < 0$ and $\frac{\delta \mathbf{h}}{\delta t} > 0$ so the particle slows down coming to a stop at $t = 2\pi$.

Again this is analogous to the motion of a mass on a spring.

You may want to again view [the Animation String Velocity](#).

6. $\frac{\delta^2 \mathbf{h}}{\delta x \delta t}$

By $\frac{\delta^2 \mathbf{h}}{\delta x \delta t}$ we mean $\frac{\delta}{\delta x} \left(\frac{\delta \mathbf{h}}{\delta t} \right)$.

Now $\frac{\delta \mathbf{h}}{\delta t}$ is the velocity of a particle of the string. It follows $\frac{\delta}{\delta x} \left(\frac{\delta \mathbf{h}}{\delta t} \right)$ is the rate at which the velocities of the particles change as we move from left to right along the string.

$$\frac{\delta^2 \mathbf{h}}{\delta x \delta t} = -\pi \sin(t) \cdot \cos(\pi x)$$

Consider what happens at $t = 0$. If $0 < x < .5$ then $\frac{\delta^2 \mathbf{h}}{\delta x \delta t} < 0$ meaning $\frac{\delta \mathbf{h}}{\delta t}$ is decreasing as we move to the right along the string. For example as we move from $x = .25$ to $x = .4$ $\frac{\delta^2 \mathbf{h}}{\delta x \delta t} < 0$ meaning the velocity is decreasing i.e. is more negative-- meaning a particle to the right of x is traveling downward faster which is necessary for the string to maintain its shape.

For $.5 < x < 1$ $\frac{\delta^2 \mathbf{h}}{\delta x \delta t} > 0$ meaning $\frac{\delta \mathbf{h}}{\delta t}$ is increasing as we move to the right along this string. For example

At $x = .75$ $\cos(\pi \cdot .75) < 0$ so $\frac{\delta^2 \mathbf{h}}{\delta x \delta t} > 0$ meaning as we move to from $.75$ to $.9$ the velocity is less negative

i.e. is increasing which means a particle to the right of x is moving slower.

[See the animation - String Velocities.](#)

Example Let $f(x, y) = x^3 \cdot \sin(y)$

Compute all second derivatives

$$f_x = 3 \cdot x^2 \sin(y)$$

$$f_y = x^3 \cos(y)$$

$$f_{xy} = 3 \cdot x^2 \cos(y)$$

$$f_{yx} = 3 \cdot x^2 \cos(y)$$

$$f_{xx} = 6 \cdot x \sin(y)$$

$$f_{yy} = -x^3 \sin(y)$$
